

Section 1: Preliminaries

1.1 Exchangeability and de Finetti's theorem

A standard situation in statistics is to be presented with a sequence of observations, and use them to make predictions about future observations. In order to do so, we need to make certain assumptions about the nature of the statistical relationships between the sequence of observations.

A common assumption is that our data are **exchangeable**, meaning that their joint probability is invariant under permutations. More concretely, we say a sequence of N observations is finitely exchangeable if $\mathbf{P}(X_1 \in A_1, X_2 \in A_2, \dots, X_N \in A_N) = \mathbf{P}(X_{\sigma(1)} \in A_1, X_{\sigma(2)} \in A_2, \dots, X_{\sigma(N)} \in A_N)$ for any permutation of the integers 1 through N , and that an infinite sequence is infinitely exchangeable if this invariance holds for all values of N .

Exercise 1.1 *Clearly, all iid sequences are exchangeable, but not all exchangeable sequences are iid. Consider an urn, containing r red balls and b blue balls. A sequence of colors is generated by repeatedly sampling a ball from the urn, noting its color, and then returning the ball, plus another ball of the same color, to the urn. Show that the resulting sequence is exchangeable, but not iid.*

Answer: I will prove this by using an example in which three balls are removed—two blue and one red. In this case, I will show that the probabilities of the three balls being removed in different orders are equivalent. This will demonstrate exchangeability (but not iid), given that the balls are not mutually independent after the first pull. Below the probabilities of $\{r, b, b\}$ and $\{b, b, r\}$ are given.

$$p(r)p(b|r)p(b|(b|r)) = \frac{r}{r+b} * \frac{b}{r+b+1} * \frac{b}{r+b+2} \quad (1.1)$$

$$p(b)p(b|b)p(r|(b|b)) = \frac{b}{r+b} * \frac{b}{r+b+1} * \frac{r}{r+b+2} \quad (1.2)$$

The above relations can be easily extended to include the set $\{b, r, b\}$, and extended beyond the 3-pull case given that the numerators and denominators of the probability functions are equivalent and all that changes is the order of the numerator. Therefore, if the *same* balls are pulled in each run, the sequence is exchangeable.

1.1.1 De Finetti's Theorem

Loosely speaking, de Finetti's Theorem states if a sequence of random variables is infinitely exchangeable, those random variables must be conditionally i.i.d. given some set of parameters. More formally,

Theorem 1.1 (de Finetti) *Let (X_1, X_2, \dots) be an infinite sequence of random variables in some space \mathcal{X} . This sequence is infinitely exchangeable if and only if there exists a probability distribution \mathbf{Q}_θ , parametrized by some random parameter $\theta \sim \nu$, such that the X_i are conditionally iid given \mathbf{Q}_θ and such that*

$$\mathbf{P}(X_1 \in A_1, X_2 \in A_2, \dots) = \int_{\Theta} \prod_{i=1}^{\infty} \mathbf{Q}_\theta(A_i) \nu(d\theta).$$

This means we can imagine that any exchangeable sequence has been generated as a sequence of i.i.d. random variables with some unknown law. This provides a motivation for Bayesian inference: We have a hierarchical model, where data are generated according to some distribution parametrized by a random (in the Bayesian context – i.e. unknown/uncertain) variable θ , and our uncertainty about θ is characterized by some distribution ν .

Let's consider the 0/1 form of de Finetti's theorem, for exchangeable sequences of binary variables:

Theorem 1.2 (de Finetti 0/1) *An infinite sequence (X_1, X_2, \dots) of binary random variables is exchangeable if and only if its distribution can be written as*

$$\begin{aligned} \mathbf{P}(X_1 = x_1, X_2 = x_2, \dots, X_N = x_N) &= \int_0^1 \prod_{i=1}^N \{\theta^{x_i} (1 - \theta)^{1-x_i}\} d\nu(\theta) \\ &= \int_0^1 \theta^k (1 - \theta)^{N-k} d\nu(\theta) \end{aligned}$$

where $k = \sum_i x_i$.

We will now work through (most of) a proof in the next two exercises.

Exercise 1.2 *We will start off with a finite sequence (X_1, \dots, X_M) . For any $N \leq M$, show that*

$$\mathbf{P}\left(\sum_{i=1}^N X_i = s \mid \sum_{i=1}^M X_i = t\right) = \frac{\binom{t}{s} \binom{M-t}{N-s}}{\binom{M}{N}}$$

Answer:

$$P(X_N = x_N) = \binom{N}{s} P(x_1, x_2, \dots, x_N) = \binom{N}{s} P(x_{\pi(1)}, x_{\pi(2)}, \dots, x_{\pi(N)}) \quad (1.3)$$

Where π represents a permutation of the original results. By exchangeability:

$$P(X_N = x_n) = P\left(\sum_N X_N = s \mid \sum_M X_M = t\right) P(X_M = x_M) \quad (1.4)$$

Therefore:

$$P\left(\sum_N X_N = s \mid \sum_M X_M = t\right) = \frac{P(X_M = x_M)}{P(X_N = x_n)} = \frac{\binom{N}{s} P(x_1, x_2, \dots, x_N)}{\binom{M}{t} P(x_1, x_2, \dots, x_M)} \quad (1.5)$$

And the above simplifies to the hypergeometric mass function:

$$P\left(\sum_N X_N = s \mid \sum_M X_M = t\right) = \frac{\binom{t}{s} \binom{M-t}{N-s}}{\binom{M}{N}} \quad (1.6)$$

We can therefore write

$$\mathbf{P}\left(\sum_{i=1}^N X_i = s\right) = \binom{N}{s} \sum_{t=s}^{M-N+s} \frac{\binom{t}{s} \binom{M-t}{N-s}}{\binom{M}{N}} \mathbf{P}\left(\sum_{i=1}^M X_i = t\right), \quad (1.7)$$

where $(x)_y = x(x-1)\dots(x-y+1)$.

Let $F_M(\theta)$ be the distribution function of $\frac{1}{M}(X_1 + \dots + X_M)$ – i.e. a step function between 0 and 1, with steps of size $\mathbf{P}(\sum_i X_i = t)$ at $t = 0, 1, \dots, M$. Then we can rewrite Equation 1.7 as

$$\mathbf{P}\left(\sum_{i=1}^N X_i = s\right) = \binom{N}{s} \int_0^1 \frac{(M\theta)_s (M(1-\theta))^{N-s}}{(M)_N} dF_M(\theta)$$

Exercise 1.3 Show that, as $M \rightarrow \infty$, we can write

$$\mathbf{P}(X_1 = x_1, \dots, X_N = x_N) \rightarrow \int_0^1 \theta^s (1-\theta)^{N-s} dF_M(\theta)$$

The proof is completed using a result (the Helly Theorem), that shows that any sequence $\{F_M(\theta); M = 1, 2, \dots\}$ of probability distributions on $[0,1]$ contains a subsequence that converges to $F(\theta)$.

Answer: I will demonstrate this by expanding each term and keeping only the largest term (since $M \rightarrow \infty$).

$$\begin{aligned} (M\theta)_s &= (M\theta)(M\theta - 1)\dots(M\theta - s + 1) = (M\theta)^s \\ (M(1-\theta))^{N-s} &= (M(1-\theta))((M(1-\theta)) - 1)\dots((M(1-\theta)) - N + s + 1) = (M(1-\theta))^{N-s} \\ (M)_N &= (M)((M-1)\dots(M-N+1)) = M^N \end{aligned} \quad (1.8)$$

Putting the largest terms back into the equation:

$$\mathbf{P}\left(\sum_{i=1}^N X_i = s\right) = \binom{N}{s} \int_0^1 \frac{M^s \theta^s (M(1-\theta))^{N-s}}{M^N} dF_M(\theta) \quad (1.9)$$

$$\mathbf{P}(X_1 = x_1, \dots, X_N = x_N) \rightarrow \int_0^1 \theta^s (1-\theta)^{N-s} dF_M(\theta) \quad (1.10)$$

1.2 The exponential family of distributions

De Finetti's theorem can be seen as a motivation for Bayesian inference. If our data are exchangeable, we know that they are iid according to some unknown probability distribution $F_\theta(X)$, which we can think of as a **likelihood function**, and that they can be represented using an mixture of such iid sequences. As we saw from the 0/1 case, the distribution over probabilities is given by the limit of the empirical distribution function. When not working in this limit, we may choose to model this distribution over the parameters of our likelihood function using a **prior** distribution $\pi(\theta)$ – ideally one that both assigns probability mass to where we expect the empirical distribution might concentrate, and for which $\int_{\Theta} F_\theta(X) \pi(d\theta)$ is tractable.

The exponential family of probability distributions is the class of distributions parametrized by θ whose density can be written as

$$p(x|\theta) = h(x) \exp\{\eta(\theta)^T T(x) - A(\eta(\theta))\}$$

where

- $\eta(\theta)$ (sometimes just written as η), is a transformation of θ that is often referred to as the **natural or canonical parameter**.

- $T(X)$ is known as a **sufficient statistic** of X . We see that $p(x|\theta)$ depends only on X through $T(X)$, implying that $T(X)$ contains all the relevant information about X .
- $A(\eta(\theta))$ (or $A(\eta)$) is known as the **cumulant function** or the **log partition function** (remember, a partition function provides a normalizing constant).

Example 1.1 (The Bernoulli distribution) A Bernoulli random variable X takes the value $X = 1$ with probability π and $X = 0$ with probability $1 - \pi$; it's density can be written:

$$\begin{aligned} p(x|\pi) &= \pi^x (1 - \pi)^{1-x} \\ &= \exp \left\{ \log \left(\frac{\pi}{1 - \pi} \right) x + \log(1 - \pi) \right\} \end{aligned}$$

By rewriting in this exponential family form, we see that

- $\eta = \frac{\pi}{1 - \pi}$
- $T(x) = x$
- $A(\eta) = -\log(1 - \pi) = \log(1 + e^\eta)$
- $h(x) = 1$

Exercise 1.4 The Poisson random variable has PDF

$$p(x|\lambda) = \frac{\lambda^x e^{-\lambda}}{x!}$$

Re-write the density of the Poisson random variable in exponential family form. What are η , $T(x)$, $A(\eta)$ and $h(x)$? What about if we have n independent samples x_1, \dots, x_n ?

Answer: Taking the exponent of the above yields:

$$p(x|\lambda) = \frac{\lambda^x e^{-\lambda}}{x!} \tag{1.11}$$

$$p(x|\lambda) = \frac{\exp(x \ln(\lambda) - \lambda)}{x!} \tag{1.12}$$

Where $\eta = \ln(\lambda)$, $T(x) = x$, $h(x) = 1/(x!)$, and $A(\eta) = \lambda = e^\eta$.

Exercise 1.5 The gamma random variable has PDF

$$p(x|\alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} x^{\alpha-1} e^{-\beta x}$$

What are the natural parameters and sufficient statistics for the gamma distribution, given n observations x_1, \dots, x_N ?

Answer: Taking the exponent of the above yields:

$$p(x|\alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} x^{\alpha-1} e^{-\beta x} \tag{1.13}$$

$$p(x|\alpha, \beta) = \exp(-\beta x + (\alpha - 1)\ln(x) + \alpha\ln(\beta) - \ln(\Gamma(\alpha))) \tag{1.14}$$

Where $\eta = \begin{bmatrix} \alpha - 1 \\ \beta \end{bmatrix}$, $h(x) = 1$, $T(x) = \begin{bmatrix} \ln(x) \\ x \end{bmatrix}$, and $A(\eta) = \ln\Gamma(\eta_1 + 1) - (\eta_1 + 1)\ln(-\eta_2)$.

1.2.1 Cumulants and moments of exponential families

We are probably most familiar with using the PDF or the CDF of a random variable to describe its distribution, but there are other representations that can be useful. The **moment generating function** $M_X(s) = \mathbb{E}[\exp(s^T x)] = \int_{\mathcal{X}} e^{s^T x} p_X(x) dx$ is the Laplace transform of the PDF $p_X(x)$. As the name suggests, we can use the moment-generating function to generate the (uncentered) moments of a random variable; the n th moment is given by

$$m_n = \left. \frac{d^n M_X}{ds^n} \right|_{s=0}$$

Exercise 1.6 *For exponential family random variables, we know that the sufficient statistic $T(X)$ contains all the information about X , so (for univariate X) we can write the moment generating function of the sufficient statistic as $\mathbb{E}[e^{sT(x)}|\eta]$. Show that the moment generating function for the sufficient statistic of an arbitrary exponential family random variable with natural parameter η can be written as*

$$M_{T(X)}(s) = \exp A(\eta + s) - A(\eta)$$

Answer: Since Probability Density Functions (PDFs) integrate to unity, the below is true:

$$M_T(s) = E[e^{sT}|\eta] = \int e^{sT} h(x) e^{\eta T - A(\eta)} dx \quad (1.15)$$

$$M_T(s) = \int h(x) e^{(s+\eta)T - A(\eta)} dx \quad (1.16)$$

$$M_T(s) = e^{A(s+\eta) - A(\eta)} \int h(x) e^{(s+\eta)T - A(\eta+s)} dx \quad (1.17)$$

$$M_T(s) = e^{A(s+\eta) - A(\eta)} \quad (1.18)$$

A related representation is the **cumulant generating function** $C_X(s) = \log \mathbb{E}[e^{s^T x}] = \log(M_X(s))$. Clearly, for exponential families this takes the form $C_{T(X)}(s) = A(\eta + s) - A(\eta)$. This explains why $A(\eta)$ is sometimes called the cumulant function! The cumulant function can be used to generate the cumulants of a distribution as

$$\kappa_n = \left. \frac{d^n C_X}{ds^n} \right|_{s=0}$$

The first three cumulants are the same as the first three central moments of the distribution – meaning, the cumulant generative function is a useful tool for calculating mean, variance and the third central moment.

Exercise 1.7 *It is usually easier to calculate mean and variance using the cumulant generating function rather than the moment generating function. Starting from the exponential family representation of the Poisson distribution from Exercise 1.4, calculate the mean and variance of the Poisson using a) the moment generating function, and b) the cumulant generating function.*

Answer:

$$p(x|\lambda) = \frac{\lambda^x e^{-\lambda}}{x!} = \frac{1}{x!} e^{x \ln(\lambda) - \lambda} \quad (1.19)$$

$$C_T(s) = A(\eta + s) - A(\eta) \quad (1.20)$$

$$(1.21)$$

Using the cumulant generating function:

$$\kappa_1 = \left. \frac{\partial C_T}{\partial s} \right|_0 = e^{\eta+s} \Big|_0 = e^\eta \quad (1.22)$$

$$\kappa_2 = \left. \frac{\partial^2 C_T}{\partial s^2} \right|_0 = e^\eta \quad (1.23)$$

If instead using the moment function:

$$\kappa_1 = \left. \frac{\partial M_T}{\partial s} \right|_0 = e^{e^{s+\eta} + s - e^\eta + \eta} \Big|_0 = e^\eta \quad (1.24)$$

$$\kappa_2 = \left. \frac{\partial^2 M_T}{\partial s^2} \right|_0 = e^{\eta+s} \Big|_0 = e^\eta \quad (1.25)$$

1.2.2 Conjugate priors

Exponential families are very important in Bayesian statistics because, for any exponential family likelihood, we can find an conjugate exponential family prior. If our likelihood takes the form

$$f(x|\eta) = h(x) \exp \{ \eta^T T(x) - A(\eta) \}$$

then a conjugate prior is given by

$$p(\eta|\xi, \nu) = g(\xi, \nu) \exp \{ \eta^T \xi - \nu A(\eta) \}$$

Below are some exercises based on common conjugate priors.

Exercise 1.8 Suppose we have N independent observations $x_1, \dots, x_N \stackrel{iid}{\sim} \text{Normal}(\mu, \sigma^2)$. If σ^2 is known and $\mu \sim \text{Normal}(\mu_0, \sigma_0^2)$, derive the posterior for $\mu|x_1, \dots, x_N$

Answer:

$$f(x|\mu) = \frac{1}{(2\pi\sigma^2)^{n/2}} \exp\left[-\frac{1}{2\sigma^2} \left(\sum_{i=1}^n (x_i - \mu)^2\right)\right] \quad (1.26)$$

$$p(\mu|\mu_o, \sigma_o^2) = -\frac{1}{\sqrt{2\pi\sigma}} \exp\left[\frac{1}{2\sigma_o} (\mu - \mu_o)^2\right] \quad (1.27)$$

$$p(\mu|x) \propto p(\mu|\mu_o, \sigma_o^2) f(x|\mu) \quad (1.28)$$

Multiplying together:

$$Posterior = \exp[-\frac{1}{2\sigma^2}(\sum_i^n (x_i^2 + \mu^2 - 2x_i\mu) - (\mu^2 + \mu_o^2 - 2\mu_o\mu))] \quad (1.29)$$

$$Posterior = \exp[\frac{\mu^2}{2}(\frac{1}{\sigma^2} + \frac{n}{\sigma_o^2}) + \mu(\frac{\mu_o}{\sigma_o^2} + \frac{\sum_i^n (x_i)}{\sigma^2}) - (\frac{\mu_o^2}{2\sigma_o^2} + \frac{\sum_i^n (x_i)}{2\sigma^2})] \quad (1.30)$$

The above needs to fit into the below format:

$$f * p = \exp[-\frac{1}{2\sigma_n^2}(\mu^2 - 2\mu\mu_n + \mu_n^2)] \quad (1.31)$$

$$f * p = \exp[-\frac{1}{2\sigma_n^2}(\mu - \mu_n)^2] \quad (1.32)$$

Matching the coefficients:

μ^2 :

$$-\frac{\mu^2}{2\sigma_n^2} = -\frac{\mu^2}{2}(\frac{1}{\sigma_o^2} + \frac{n}{\sigma^2}) \quad (1.33)$$

σ_n^2 :

$$\frac{1}{\sigma^2} = \frac{1}{\sigma_o^2} + \frac{n}{\sigma_o^2}\sigma_n^2 = \frac{\sigma^2\sigma_o^2}{n\sigma_o^2 + \sigma^2} = \frac{1}{\frac{n}{\sigma^2} + \frac{1}{\sigma_o^2}} \quad (1.34)$$

μ :

$$\frac{-2\mu\mu_n}{-2\sigma_n^2} = \mu(\frac{\sum_i^n (x_i)}{\sigma^2} + \frac{\mu_o}{\sigma_o^2}) \quad (1.35)$$

$$\frac{\mu_n}{\sigma_n^2} = \frac{\sum_i^n (x_i)}{\sigma^2} + \frac{\mu_o}{\sigma_o^2} \quad (1.36)$$

$$\frac{\mu_n}{\sigma_n^2} = \frac{\sigma_o^2 n \bar{x} + \sigma^2 \mu}{\sigma^2 \sigma_o^2} \quad (1.37)$$

Completing the square:

$$\mu_n = \frac{\sigma^2}{n\sigma_o^2 + \sigma^2}\mu_o + \frac{n\sigma_o^2 \bar{x}}{n\sigma_o^2 + \sigma^2} \quad (1.38)$$

$$\mu_n = \sigma_n^2(\frac{\mu_o}{\sigma_o^2} + \frac{n\bar{x}}{\sigma^2}) \quad (1.39)$$

Using the relation $1/\sigma^2 = \lambda$:

$$p(\mu|x, \lambda) = Normal(\mu|\mu_n, \lambda_n) \quad (1.40)$$

$$\lambda_n = \lambda_o + n\lambda \quad (1.41)$$

$$\mu_n = \frac{\bar{x}n\lambda + \mu_o\lambda_o}{\lambda_n} \quad (1.42)$$

Exercise 1.9 Now, let's assume $x_1, \dots, x_N \stackrel{iid}{\sim} \text{Normal}(\mu, \sigma^2)$ with known mean μ but unknown variance σ^2 . Let's express the likelihood in terms of the precision, $\omega = 1/\sigma^2$:

$$f(x_i|\mu, \omega) = \sqrt{\frac{\omega}{2\pi}} \exp\left\{-\frac{\omega}{2}(x_i - \mu)^2\right\}$$

Let ω have a gamma prior (this is also known as putting an inverse-gamma prior on σ^2):

$$p(\omega) = \frac{\beta^\alpha}{\Gamma(\alpha)} \omega^{\alpha-1} e^{-\beta\omega}$$

Derive the posterior distribution for ω

Answer: The likelihood function of all n observations:

$$\prod_{i=1}^n \sqrt{\frac{\omega}{2\pi}} \exp\left[-\frac{\omega}{2}(x_i - \mu)^2\right] \quad (1.43)$$

$$\left(\frac{\omega}{2\pi}\right)^{n/2} \exp\left[-\frac{\omega}{2} \sum_{i=1}^n (x_i - \mu)^2\right] \quad (1.44)$$

Now solving for the posterior:

$$\text{posterior} \propto \text{likelihood} * \text{prior} \quad (1.45)$$

$$\text{posterior} \propto \omega^{\alpha+(n/2)-1} \exp\left[-\omega\left(\frac{1}{2} \sum_{i=1}^n (x_i - \mu)^2 + \beta\right)\right] \quad (1.46)$$

$$\text{Gamma}\left(\alpha + \frac{n}{2}, \frac{1}{2} \sum_{i=1}^n (x_i - \mu)^2 + \beta\right) \quad (1.47)$$

Exercise 1.10 Let's assume $x \sim \text{Normal}(0, \sigma^2)$ and that $\sigma^2 \sim \text{InvGamma}(\alpha, \beta)$ (i.e. $1/\sigma^2 \sim \text{Gamma}(\alpha, \beta)$). Show that the marginal distribution of x is given by a Student's t distribution.

Answer:

Using the laplace transform:

$$\int_{\omega} \mathcal{L}(x, \omega) d\omega = \int_{\omega} \sqrt{\frac{\omega}{2\pi}} \frac{\beta^\alpha}{\Gamma(\alpha)} \omega^{\alpha+1/2-1} e^{-\omega(\beta+(x-\mu)^2)} d\omega \quad (1.48)$$

$$= \frac{\beta \Gamma(\alpha + 1/2)}{2\pi \Gamma(\alpha) (\beta + (1/2)(x - \mu)^2)^{\alpha+(1/2)}} \int_{\omega} \frac{(\beta + (1/2)(x - \mu)^2)^{\alpha+(1/2)}}{\Gamma(\alpha + (1/2))} \omega^{\alpha+(1/2)-1} e^{-\omega(\beta+(x-\mu)^2)} d\omega \quad (1.49)$$

The integral in the above equation integrates to 1. Therefore, the coefficient outside of the integral can be cast to a student's t distribution. With $\mu = 0$, the above becomes:

$$\frac{1+x^2}{\sqrt{2\pi}2\beta} \frac{\Gamma(\alpha + (1/2))}{\Gamma(\alpha)} \quad (1.50)$$

Re-arranging into the t-distribution form (where the top equation is the general form and the bottom equation is specific to this problem):

$$\frac{\Gamma(\frac{\nu+1}{2})}{\sqrt{\nu\pi}\Gamma(\frac{\nu}{2})} \left(1 + \frac{x^2}{\nu}\right)^{-\frac{\nu+1}{2}} \quad (1.51)$$

$$\frac{\Gamma(\frac{2\alpha+1}{2})}{\sqrt{2\alpha\pi}\Gamma(\frac{2\alpha}{2})} \left(1 + \frac{x^2}{2\alpha}\right)^{-\frac{2\alpha+1}{2}} \quad (1.52)$$

1.3 Multivariate normal distribution

So far, we have looked at univariate random variables - particularly, the univariate normal random variable, which is characterized by its mean and variance. We will often work with the multivariate normal distribution, a natural generalization characterized by a mean vector and a covariance matrix.

Exercise 1.11 (covariance matrix) *The covariance matrix Σ of a vector-valued random variable x is the matrix whose entries $\Sigma(i, j) = \text{cov}(x_i, x_j)$ are given by the covariance between the i th and j th elements of x , giving*

$$\Sigma = \mathbb{E}[(x - \mu)(x - \mu)^T]$$

Show that a) $\Sigma = E[xx^T] - \mu\mu^T$; b) if the covariance of x is σ , then the covariance of $Ax + b$ is $A\Sigma A^T$

Answer: Solving part a:

$$\Sigma = E[(x - \mu)(x - \mu)^T] = E[(x - \mu)(x^T - \mu^T)] \quad (1.53)$$

$$\Sigma = E[xx^T] - E[\mu\mu^T] - \frac{2\mu E[x^T]}{\mu^T} \quad (1.54)$$

$$\Sigma = E[xx^T] - \mu\mu^T \quad (1.55)$$

Solving part b:

$$\text{cov}(Ax + b) = E[(Ax + b - E[Ax] - E[b])(Ax + b - E[Ax] - E[b])^T] \quad (1.56)$$

$$\text{cov}(Ax + b) = E[(Ax - AE[x])(Ax - AE[x])^T] \quad (1.57)$$

$$\text{cov}(Ax + b) = AE[(x - E[x])(x - E[x])^T]A^T \quad (1.58)$$

$$\text{cov}(Ax + b) = A\Sigma A^T \quad (1.59)$$

Exercise 1.12 (Standard multivariate normal) *The simplest multivariate normal, known as the standard multivariate normal, occurs where the entries of x are independent and have mean 0 and variance 1. a) What is the moment generating function of a univariate normal, with mean m and variance v^2 ? b) Express the PDF and moment generating function of the standard multivariate normal, in vector notation.*

Answer: Part a:

$$M_x(t) = E[e^{tx}] \quad (1.60)$$

$$M_x(t) = e^{t^2/2} \quad (1.61)$$

$$(1.62)$$

Part b:

$$M_z(t) = E[e^{t^T z}] = E[\exp(\sum t_i z_i)] \quad (1.63)$$

$$M_z(t) = E[\exp(\prod_{i=1}^n t_i z_i)] \quad (1.64)$$

$$M_z(t) = \exp((1/2) \sum_{i=1}^n t_i^2) \quad (1.65)$$

$$M_z(t) = \exp((1/2)t^T t) \quad (1.66)$$

Exercise 1.13 (Multivariate normal) *A random vector x has multivariate normal distribution if and only if every linear combination of its elements is univariate normal, i.e. if the scalar value $z = a^T x$ is normally distributed for all possible x . Prove that this implies that x is multivariate normal if and only if its moment generating function takes the form $M_X(s) = \exp\{s^T \mu + s^T \Sigma s\}$, where μ and Σ are the mean and covariance of x . Hint: We know the moment generating function of z in terms of the mean and variance of z , from the previous question...*

Answer:

$$M_{a^T x}(s) = E[e^{a^T x s}] = E[e^{s a^T x}] \quad (1.67)$$

$$M_{a^T x}(s) = e^{s a^T \mu + (1/2) s a^T \Sigma a s} \quad (1.68)$$

$$M_{a^T x}(s) = e^{s \mu^* + (1/2) s^2 \sigma^*} \quad (1.69)$$

$$\mu^* = a^T \mu, \quad \sigma^* = \sqrt{a^T \Sigma a} \quad (1.70)$$

Exercise 1.14 (Relationship to standard multivariate normal) *An equivalent statement is that a random vector x has multivariate normal distribution if and only if it can be written in the form*

$$x = Dz + \mu$$

for some matrix D , real-valued vector μ , and vector z distributed according to a standard multivariate normal. Express the moment generating function of x in terms of D , and uncover the relationship between D and Σ . Use this result to suggest a method for generating multivariate normal random variables, if you have a method for generating Normal(0,1) univariate random variables.

Answer: Relating Σ and D :

$$E[Dz + \mu] = \mu \quad (1.71)$$

$$\text{cov}(Dz + \mu) = \text{cov}(Dz) \quad (1.72)$$

$$\text{cov}(Dz + \mu) = D \text{cov}(z) D^T \quad (1.73)$$

$$\Sigma = D D^T \quad (1.74)$$

Use this result to suggest a method for generating multivariate normal random variables, if you have a method for generating Normal(0,1) univariate random variables:

$$\Sigma = U \Lambda U^T = V V^T \quad (1.75)$$

The above is possible via diagonalization and can work to generate samples in a multivariate normal.

Exercise 1.15 Use the result from the previous question to show that the PDF of a multivariate normal random vector $x \sim \text{Normal}(\mu, \Sigma)$ takes the form

$$p(x) = \frac{1}{(2\pi)^{n/2}} |\Sigma|^{-1/2} \exp \left\{ -\frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu) \right\},$$

by using a change-of-variables from the standard multivariate normal distribution.

Answer:

$$x = V(x) = Dz + \mu = U(z) \quad (1.76)$$

$$z = V(x) = D^{-1}(x - \mu) \quad (1.77)$$

$$f_z(z) = f_x(x) \nu'(x) \quad (1.78)$$

$$f_z = (2\pi)^{-n/2} |D| e^{-(1/2)(x-\mu)^T D^{-1} \Sigma^{-1} D^{-1} (x-\mu)} \quad (1.79)$$

1.3.1 Manipulation of multivariate normals

Like its univariate counterpart, the multivariate normal distribution is closed under a number of operations, which we will explore here.

Exercise 1.16 (marginal distribution) Let us assume that $x \sim \text{Normal}(\mu, \Sigma)$, and let us partition x into 2 components x_1 and x_2 . Let us similarly partition μ and σ so that

$$\mu = (\mu_1, \mu_2)^T \quad \Sigma = \begin{pmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{pmatrix} = \begin{pmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{12}^T & \Sigma_{22} \end{pmatrix}$$

Derive the marginal distribution of x_1 .

Answer: First defining the precision matrix, $V = \begin{pmatrix} V_{11} & V_{12} \\ V_{12}^T & V_{22} \end{pmatrix}$, and then re-expressing the exponent above:

$$x^T \Sigma^{-1} x = x_1^T V_{11} x_1 + x_1^T V_{12} x_2 + x_2^T V_{21} x_1 + x_2^T V_{22} x_2 \quad (1.80)$$

Completing the square to get in this form:

$$x^T \Sigma^{-1} x = (x_2 - a)^T A (x_2 - a) + b \quad (1.81)$$

The coefficients become: $A = V_{22}$, $a = -V_{22}^{-1} V_{21} x_1$, and $b = x_1^T (V_{11} - V_{21}^T V_{22}^{-1} V_{21}) x_1$

Therefore:

$$x_2 | x_1 = x_1 \mathcal{N}(-V_{22}^{-1} V_{21} x_1, V_{22}^{-1}) \quad (1.82)$$

$$x_1 \mathcal{N}(0, (V_{11} - V_{21}^T V_{22}^{-1} V_{21})^{-1}) \quad (1.83)$$

Using the result from the following problem:

$$x_1 \mathcal{N}(0, \Sigma_{11}) \quad (1.84)$$

Exercise 1.17 (Precision matrix) *Earlier, we chose to express a univariate normal random variable in terms of its precision, to make math easier. We can also express a multivariate normal in terms of a precision matrix $\Omega = \Sigma^{-1}$. Partition Ω as*

$$\Omega = \begin{pmatrix} \Omega_{11} & \Omega_{12} \\ \Omega_{12}^T & \Omega_{22} \end{pmatrix}$$

and express Ω_{11} , Ω_{12} and Ω_{22} in terms of Σ_{11} , Σ_{12} and Σ_{22} . Hint: You'll need the matrix inversion lemma

Answer: Starting from the relation $\Sigma\Sigma^{-1} = \Sigma\Omega = I$, where I is a properly sized matrix based on the size of the covariance matrix. The four relations below were found through matrix multiplication:

$$\Omega_{11} = (\Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1} \quad (1.85)$$

$$\Omega_{22} = (-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12} + \Sigma_{22})^{-1} \quad (1.86)$$

$$\Omega_{21} = -\Sigma_{22}^{-1}\Sigma_{21}(\Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21})^{-1} \quad (1.87)$$

$$\Omega_{12} = -\Sigma_{11}^{-1}\Sigma_{12}(\Sigma_{22} - \Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12})^{-1} \quad (1.88)$$

Exercise 1.18 (Conditional distribution) *The conditional distribution of $x_1|x_2$ is also normal, with mean $\mu_1 + \Sigma_{12}\sigma_{22}^{-1}(x_2 - \mu_2)$ and covariance $\Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{12}^T$. Prove this for the case where μ is zero (the general case isn't really harder, just more tedious). Hint: ignore any constants that don't involve x_1 . You might want to work with the log conditional density.*

Answer: From problem 16, we know that $x_2|x_1 = x_1 \mathcal{N}(-\Omega_{22}^{-1}V_{21}x_1, V_{22}^{-1})$. The distribution of $x_1|x_2$ can be evaluated from the joint distribution $p(x) = p(x_1, x_2)$, where x_2 is fixed at an observed value.

$$\begin{aligned} & -(1/2)(x - \mu)^T \Sigma^{-1} (x - \mu) = \\ & -(1/2)(x_1 - \mu_1)^T \Omega_{11} (x_1 - \mu_1) \\ & -(1/2)(x_1 - \mu_1)^T \Omega_{12} (x_2 - \mu_2) \\ & -(1/2)(x_2 - \mu_2)^T \Omega_{21} (x_1 - \mu_1) \\ & -(1/2)(x_2 - \mu_2)^T \Omega_{22} (x_2 - \mu_2) \end{aligned} \quad (1.89)$$

Completing the square with the above equation aiming to get the form: $-(1/2)x^T \Sigma^{-1} x + x^T \Sigma^{-1} \mu + \text{const}$, by term:

1st order in x_1 (using the relation $\Omega_{21}^T = \Omega_{12}$):

$$\Sigma^{-1} \mu = x_1^T (\Omega_{11} \mu_1 - \Omega_{12} (x_2 - \mu_2)) \quad (1.90)$$

$$\mu = \mu_1 + \Omega_{11}^{-1} \Omega_{12} (x_2 - \mu_2) \quad (1.91)$$

2nd order in x_1 :

$$-(1/2)x_1^T \Omega_{11} x_1 \quad (1.92)$$

$$\Sigma_{x_1|x_2} = \Omega_{11}^{-1} \quad (1.93)$$

Σ :

$$\mu = \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2) \quad (1.94)$$

$$\mu = \mu_1 + \Sigma_{12}\sigma_{22}^{-1}(x_2 - \mu_2) \quad (1.95)$$

$$\Sigma = \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21} \quad (1.96)$$

$$\Sigma = \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{12}^T \quad (1.97)$$

$$(1.98)$$

1.4 Frequentist estimation and uncertainty quantification

In this section, we're going to go over basic frequentist approaches to inference, with a focus on multiple linear regression (since we're next going to look at Bayesian regression). Some of this should be familiar to you, although we will go into quite some depth. Throughout the remainder of this section, we are going to assume our data follow a linear model, of the form

$$y_i = x_i^T \beta + \epsilon_i, \quad i = 1, \dots, N$$

There are a number of options for estimating β . Three commonly used techniques are:

1. **Method of Moments** Select $\hat{\beta}$ so that the empirical moments of the observations match the theoretical moments.
2. **Maximum likelihood** Assume a model for generating the ϵ_i , and find the value of $\hat{\beta}$ that maximizes the likelihood.
3. **Loss function:** Construct a loss function between the y_i and $x_i^T \hat{\beta}$, and minimize that loss function.

Exercise 1.19 (method of moments) *To obtain the theoretical moments, we can assume that $E[y_i|x_i] = x_i^T \beta$, implying that the covariance between the predictors x_i and the residuals is zero. By setting the sample covariance between the x_i and the ϵ_i to zero, derive a method of moments estimator $\hat{\beta}_{MM}$*

Answer:

$$\text{cov}(x, \epsilon) = 0 \quad (1.99)$$

$$E[x\epsilon] - E[x]E[\epsilon] = 0 = E[x^T \epsilon] \quad (1.100)$$

$$E[x(y - x\beta)] = 0 \quad (1.101)$$

$$E[xy - x^T x \beta] = 0 \quad (1.102)$$

$$\hat{\beta}_{MM} = \left(\sum_{i=1}^N x_i x_i^T \right)^{-1} \sum_{i=1}^N (x_i y_i) \quad (1.103)$$

Exercise 1.20 (maximum likelihood) *Show that, if we assume $\epsilon_i \sim \text{Normal}(0, \sigma^2)$, then the ML estimator $\hat{\beta}_{ML}$ is equivalent to the method of moments estimator.*

Answer: Minimizing the negative log-likelihood function $K + \frac{1}{2\sigma^2} \sum_{i=1}^N (y_i - x_i^T \beta)^2$ leads to the solution:

$$\hat{\beta}_{ML} = \left(\sum_{i=1}^N x_i x_i^T \right)^{-1} \sum_{i=1}^N (x_i y_i) \quad (1.104)$$

Exercise 1.21 (Least squares loss function) Show that if we assume a quadratic loss function, i.e. $\hat{\beta}_{LS} = \arg \min_{\beta \in \mathbb{R}^p} \sum_{i=1}^N (y_i - x_i^T \beta)^2$, we recover the same estimator again.

Answer: To find $\hat{\beta}_{LS}$, the derivative of the quadratic loss function was taken (with the sum terms omitted for clarity):

$$\frac{\partial}{\partial \beta} = \frac{\partial}{\partial \beta} (y_i - x_i \beta)^T (y_i - x_i \beta) \quad (1.105)$$

$$= \frac{\partial}{\partial \beta} (y_i^T y_i - x_i^T \beta y_i - y_i x_i \beta + x_i^T x_i \beta^2) \quad (1.106)$$

$$\hat{\beta}_{LS} = \left(\sum_{i=1}^N x_i x_i^T \right)^{-1} \sum_{i=1}^N (x_i y_i) \quad (1.107)$$

Exercise 1.22 (Ridge regression) We may wish to add a regularization term to our loss term. For example, ridge regression involves adding an L2 penalty term, so that

$$\hat{\beta}_{ridge} = \arg \min_{\beta \in \mathbb{R}^p} \sum_{i=1}^N (y_i - x_i^T \beta)^2 \text{ s.t. } \sum_{j=1}^p \beta_j^2 \leq t$$

for some $t \geq 1$.

Reformulate this constrained optimization using a Lagrange multiplier, and solve to give an expression for $\hat{\beta}_{ridge}$. Comparing this with the least squares estimator, comment on why this estimator might be preferred in practice.

Answer: Solving by method of Lagrange multipliers ($\lambda \geq 0$), with function $J(\beta)$ representing the Lagrangian:

$$J(\beta) = (y_i - x_i \beta)^T (y_i - x_i \beta) + \lambda (\beta^T \beta - t) \quad (1.108)$$

$$\frac{\partial J}{\partial \beta} = -2x^T (y - x\beta) + 2\lambda \beta = 0 \quad (1.109)$$

$$\hat{\beta}_{ridge} = (x^T x + \lambda I_\beta)^{-1} x^T y \quad (1.110)$$

$$\hat{\beta}_{ridge} = \omega \hat{\beta}_{LS} \quad (1.111)$$

$$\omega = (x x^T + \lambda I_\beta)^{-1} x^T x \quad (1.112)$$

This estimator might be preferred in practice because it penalizes the estimates in such a way that less influential features of the data are penalized more. In addition, when we do ridge regression we add a term to $\hat{\beta}_{Ridge}$ such that it is now invertible since all columns are now linearly independent, something which is not guaranteed with the least squares method.

1.4.1 Uncertainty quantification

In a frequentist context, we typically quantify our uncertainty by looking at the sampling distribution of our estimator. Let's assume that our errors are normally distributed, i.e. (in vector notation)

$$y = X\beta + \epsilon, \quad \epsilon \sim \text{Normal}(0, \sigma^2 I)$$

Exercise 1.23 What is the sampling distribution for $\hat{\beta}_{LS}$ ($= \hat{\beta}_{MM} = \hat{\beta}_{ML}$)?

Answer:

$$\hat{\beta}_{LS} = (x^T x)^{-1} x^T y = \beta + (x^T x)^{-1} x^T \epsilon \quad (1.113)$$

$$E[\hat{\beta}_{LS}|x] = \beta + E[(x^T x)^{-1} x^T \epsilon|x] = \beta \quad (1.114)$$

$$\text{var}(\hat{\beta}_{LS}|x) = E[(\hat{\beta}_{LS} - \beta)(\hat{\beta}_{LS} - \beta)^T|x] \quad (1.115)$$

$$= E[(x^T x)^{-1} x^T \epsilon \epsilon^T x (x^T x)^{-1}|x] \quad (1.116)$$

$$\text{var}(\hat{\beta}_{LS}|x) = \sigma^2 (x^T x)^{-1} \quad (1.117)$$

Exercise 1.24 How about the sampling distribution for $\hat{\beta}_{ridge}$?

Answer:

The mean of $\hat{\beta}_{ridge}$ is given by:

$$\mu = E[\hat{\beta}_{ridge}|x] = E[W \hat{\beta}_{LS}|x] = W \beta \quad (1.118)$$

Where $W = (x^T x + \lambda I)^{-1} x^T x$.

Exercise 1.25 The two exercises above assumed the residual variance σ^2 is known. This is unlikely to be the case. Propose a strategy for estimating the standard error of $\hat{\beta}_{LS}$ from data, when σ^2 is unknown. Implement it in R, and test it on the dataset **Prestige** in the R package **cars** (there's a starter script, **prestige.R** on Github). Do you get the same standard errors as the built-in function **lm**?

Answer: I propose to use the mean-squared error (MSE) which, in this case, is represented below:

$$MSE_{\hat{\theta}} = E[\hat{\theta} - \theta]^2 = \text{Var}(\hat{\theta}) + (E(\hat{\theta}) - \theta)^2 \quad (1.119)$$

$$MSE_{\hat{\theta}} = \frac{SSE}{n - p} \quad (1.120)$$

$$MSE_{\hat{\theta}} = \frac{(y - \hat{y})^T (y - \hat{y})}{n - p} \quad (1.121)$$

In this case, $(E(\hat{\theta}) - \theta)^2$ represents the bias. However, the expected value of the estimator is the actual value, β . The bias is zero and the MSE is therefore a good method of estimating the standard error of $\hat{\beta}_{LS}$. The parameters n and p represent the sample size and the number of independent variables, respectively.

1.4.2 Propagation of uncertainty

Let's now consider the general case where we have a point estimate $\hat{\theta} = (\hat{\theta}_1, \dots, \hat{\theta}_P)^T$ to some set of parameters $\theta = (\theta_1, \dots, \theta_P)^T$, and we have an estimate $\hat{\Sigma}$ to the covariance matrix of the sampling distribution of $\hat{\theta}$. If we want to describe our uncertainty about the individual θ_i (as was the case for calculating standard errors in the regression problems above), we can look at the diagonal terms in the covariance matrix, $\hat{\Sigma}_{ii} = \hat{\sigma}_i^2$. If we care, more generally, about a *function* of the θ_i , however, the cross terms will become important.

Exercise 1.26 Let's assume we care about $f(\theta) = \sum_i \theta_i$. What is the standard error of $f(\theta)$?

Answer:

$$Var(f(\theta)) = Var(\sum_i \theta_i) = \sum_i \sum_j Cov(\theta_i, \theta_j) \quad (1.122)$$

$$Var(f(\theta)) = \sum_i Var(\theta_i) + \sum_{i \neq j} Cov(\theta_i, \theta_j) \quad (1.123)$$

$$SE_{f(\theta)} = \sqrt{Var(f(\theta))} \quad (1.124)$$

Exercise 1.27 How about the standard error of some arbitrary non-linear function $f(\theta)$? Hint: Try a Taylor expansion

Answer: Using a Taylor Series Expansion to represent $f(\theta)$:

$$f(\theta) = f(\hat{\theta}) + \left. \frac{\partial f(\theta)}{\partial \theta} \right|_{\theta=\hat{\theta}} (\theta - \hat{\theta}) + \dots + \quad (1.125)$$

$$f(\theta) = f(\hat{\theta}) + \left. \frac{\partial f(\theta)}{\partial \theta} \right|_{\theta=\hat{\theta}} (\theta) - \left. \frac{\partial f(\theta)}{\partial \theta} \right|_{\theta=\hat{\theta}} (\hat{\theta}) + \dots + \quad (1.126)$$

$$Var(f(\theta)) = \left. \frac{\partial f(\theta)}{\partial \theta} \right|_{\theta=\hat{\theta}} Cov(\theta) \left. \frac{\partial f(\theta)}{\partial \theta} \right|_{\theta=\hat{\theta}} \quad (1.127)$$

$$SE_{f(\theta)} = \sqrt{Var(f(\theta))} \quad (1.128)$$

I note that the expansion is centered on $\hat{\theta}$, but that $\theta = E[\hat{\theta}]$, and therefore the expansion is centered on a zero-bias point.
